

**Documentation of statistics for  
Construction cost index for residential buildings 2014**

## 1 Introduction

The purpose of the construction cost index for residential buildings is to measure the development in construction costs. The present construction cost index is published from the first quarter 2003 and replaces the former construction cost index which has been published from 1987 until the second quarter 2003.

## 2 Statistical presentation

The construction cost index for residential buildings is also divided into an index for one-family houses and one for multi-family houses. All indices are further more broken down into eight sub-indices by profession and six sub-indices by building parts. Both the total indices and the sub-indices are divided into material and labour costs.

### 2.1 Data description

The Construction Cost Index for residential buildings measures the development in the costs of constructing a new residential building. Indices are produced for the total construction of residential building and separate indices are published for one-family houses and multi-family houses.

For each of these three categories more detailed sub-indices by profession and building parts are published:

Sub-indices by profession:

- Earth- and concrete work
- Concrete slab work
- Bricklaying
- Carpentry
- Joinery
- Painting
- Heating and sanitary engineering
- Electrical work

Sub-indices by building parts:

- Sub-grade
- Raw buildings/carcass
- Completion of buildings
- Heating and sanitary installations
- Electrical and mechanical installations
- Fixtures

### 2.2 Classification system

The index covers residential buildings in NACE Rev. 2 Section F, and CC Groups 111 and 112 in Classification of Types of Construction.

### **2.3 Sector coverage**

The index covers residential buildings in NACE Rev. 2 Section F, and CC Groups 111 and 112 in Classification of Types of Construction. For calculating the Construction Cost Index 8 representative buildings are used - 3 one family dwellings, 2 two-family dwellings and 3 multi-family dwellings.

### **2.4 Statistical concepts and definitions**

**Labor Costs:** The price concept of labor costs is the actual earnings plus other labor costs, including employers' payments of social contributions. Only the labor costs of persons directly involved in the construction process are included.

**Material prices:** The concept of material prices for imported commodities is actual transaction prices c.i.f. excluding all duties and taxes on the goods. For commodities for the home market the concept of material prices is actual transaction prices ex producer, excluding VAT and excise duties, and taking both general and specific discounts into consideration

### **2.5 Statistical unit**

The indices are published for total construction of residential buildings.

### **2.6 Statistical population**

The indices represent the construction of residential buildings in all of Denmark.

### **2.7 Reference area**

Denmark.

### **2.8 Time coverage**

2003-

### **2.9 Base period**

2003=100

### **2.10 Unit of measure**

Indices.

### **2.11 Reference period**

The construction cost index for residential buildings is calculated quarterly for the 15th of February, 15th of May, 15th of August and 15th of November. The reference periods are, the 1st quarter by the 15th of February, the 2nd quarter by the 15th of May, the 3rd quarter by the 15th of August and the 4th quarter by the 15th of November.

### **2.12 Frequency of dissemination**

The statistics are published on a quarterly basis.

### **2.13 Legal acts and other agreements**

Data are collected in accordance with the Act on Statistics Denmark. Council Regulation (EC) No 1165/98 and Commission Regulation (EC) No 588/2001.

### **2.14 Cost and burden**

There is no direct response burden since the data are collected by others.

### **2.15 Comment**

Further information on the construction cost index for residential buildings is available in Danish at [www.dst.dk/byggeindeks](http://www.dst.dk/byggeindeks).

## **3 Statistical processing**

The Construction cost index is based in eight actual constructions. The constructions are typical for the construction of residential building in Denmark and are selected on the basis of an analysis of the current construction. The costs of the eight constructions forms the weights of the indices. These weights are used to weigh together the prices of the cost components. For the construction cost index price data that has already been collected by others in Statistics Denmark is used.

### **3.1 Source data**

The construction cost index is based on eight concrete buildings:

- Three one-family houses
- One terraced house
- One semi-detached house
- Three multi-family houses

The data for the eight types of buildings are obtained from five different contractors of different size and geographic location. Prices for materials and equipment are mainly collected from the Price Index for Domestic Supply. The prices are collected every month and are collected from producers and importers, of the declaration of contents for Price Index for Domestic Supply. The prices for the total labour costs are mainly collected from the Indices of Average Earnings for the Private Sector. The prices are collected each quarter and refer to the second month of the quarter, of the declaration of contents for Indices of Average Earnings for Private Sector.

### **3.2 Frequency of data collection**

Quarterly.

### **3.3 Data collection**

Material prices are collected for the Danish Producer Price Index. The Construction Cost Index uses PPI-prices belonging to NACE Rev. 2 Section F. There are about 1200 material prices forming about 160 representative material goods. Labor Costs are collected for the Danish indices for average earnings in the private sector. The Construction Cost Index uses earnings for NACE Rev. 2 Section F.

### **3.4 Data validation**

The data validation is handled by the Price Index for Domestic Supply and Indices of Average Earnings for the Private Sector. The first validation of price data happens when prices arrive. Here they are tested for unusual changes. The prices that do not pass the threshold value will be checked manually by the staff and accepted only if the firms can verify the change. When all prices are received, the system generates a list that includes all price changes and a measure of how these affects the elementary aggregates. The last validation is a visual inspection of all index tables.

### **3.5 Data compilation**

The construction cost index is based on eight concrete buildings:

- Three one-family houses
- One terraced house
- One semi-detached house
- Three multi-family houses

The data for the eight types of buildings are obtained from five different contractors of different size and geographic location. Prices for materials and equipment are mainly collected from the Price Index for Domestic Supply. The prices are collected every month and are collected from producers and importers, of the declaration of contents for Price Index for Domestic Supply. The prices for the total labour costs are mainly collected from the Indices of Average Earnings for the Private Sector. The prices are collected each quarter and refer to the second month of the quarter, of the declaration of contents for Indices of Average Earnings for Private Sector.

### **3.6 Adjustment**

No corrections are made.

## **4 Relevance**

The index is used for contract regulation and to follow the economic development in construction costs. The users of the construction cost index are construction organisations, contractors, building owners, lawyers, public authorities and the EU.

### **4.1 User Needs**

The construction cost index has two primary purposes. The index is used for contract regulation and to follow the economic development in construction costs. The users of the construction cost index are construction organisations, contractors, building owners, lawyers, public authorities and the EU.

### **4.2 User Satisfaction**

No information is collected on user satisfaction.

### **4.3 Data completeness rate**

The statistics fulfill the demands set by Eurostat.

## **5 Accuracy and reliability**

The construction cost index for residential buildings covers the typical house building in Denmark. The eight concrete buildings have been chosen on the basis of an analysis of the typical house building from the Central Register of Buildings and Dwellings (BBR). Prices for materials and equipment are mainly collected from the Price Index for Domestic Supply, cf. the declaration of contents for Price Index for Domestic Supply. The prices for the total labour costs are mainly collected from the Indices of Average Earnings for the Private Sector, cf. the declaration of Indices of Average Earnings for the Private Sector. All prices are collected by questionnaires. When calculating the development in construction costs, only materials, equipment and persons that are present in two consecutive quarters are included. The collected data are subject to different types of practical controls, by an investigation of the collected data.

Measures on accuracy are not available.

### **5.1 Overall accuracy**

The index is based on the development of about 200 representative goods which is split up into about 20 work functions, about 170 types of materials and about 15 types of equipment. To each representative goods a number of prices/goods are attached. The representative goods are chosen from the building accounts for the eight buildings and are chosen according to a principle of importance and representatively.

### **5.2 Sampling error**

Not relevant for these statistics.

### **5.3 Non-sampling error**

Not relevant for these statistics.

### **5.4 Quality management**

Statistics Denmark follows the recommendations on organisation and management of quality given in the Code of Practice for European Statistics (CoP) and the implementation guidelines given in the Quality Assurance Framework of the European Statistical System (QAF). A Working Group on Quality and a central quality assurance function have been established to continuously carry through control of products and processes.

### **5.5 Quality assurance**

Statistics Denmark follows the principles in the Code of Practice for European Statistics (CoP) and uses the Quality Assurance Framework of the European Statistical System (QAF) for the implementation of the principles. This involves continuous decentralized and central control of products and processes based on documentation following international standards. The central quality assurance function reports to the Working Group on Quality. Reports include suggestions for improvement that are assessed, decided and subsequently implemented.

## 5.6 Quality assessment

Overall the Construction Cost index for residential buildings is assessed to be of good quality.

## 5.7 Data revision - policy

Statistics Denmark revises published figures in accordance with the [Revision Policy for Statistics Denmark](#). The common procedures and principles of the Revision Policy are for some statistics supplemented by a specific revision practice.

## 5.8 Data revision practice

Only final statistics are calculated.

## 6 Timeliness and punctuality

The Statistic is quarterly, primo march (Q\*4), medio June (Q1), primo September (Q2) and primo December (Q3).

### 6.1 Timeliness and time lag - final results

The construction cost index for residential buildings is published quarterly at the beginning of March (4th quarter), the middle of June (1st quarter), the beginning of September (2nd quarter) and the beginning of December (3rd quarter).

### 6.2 Punctuality

The statistics are generally published without delay in relation to the scheduled publication date.

## 7 Comparability

See "Comparability over time (QPI/CC for U)".

### 7.1 Comparability - geographical

Construction Costs Indices for Residential Buildings is regulated by the EU, thus, all EU countries must transmit indices to Eurostat. The Construction Costs Indices for Residential Buildings is directly comparable to the indices produced by other EU-countries for this statistic.

### 7.2 Comparability over time

It is possible to chain and compare the new construction cost index for residential buildings with the former construction cost index. However, when comparing the two indices it should be borne in mind that it is not the development of prices for similar buildings that are compared but different kinds of buildings that are constructed using different techniques, materials and in periods with different legal demands. This means that not only the weighting scheme but also the methods for collecting prices and calculating the indices are different.

*There have been changes the following years:*

The first construction cost index was published in 1920 and was an *index for smallholding* (indeks for husmandsbrug). The index had base year in 1914. The house was not very well described. Only that it contained 3 rooms, kitchen, laundry and stable. Because of that there were great inequalities in the data reported by the cost surveyors.

In 1926 a new collection of information about a specific type of house was started. By that means it was possible to follow the price development independent of any improvements of the furniture in the house. This index was revised in 1959 when it was decided to use a farmhouse and a farm building from a type book of the ministry of agriculture. 1959 was base year. Calculation of this index was finished in 1970.

In 1940 a new monthly index for a block of flats was published. This index should measure the development in the costs of residential construction. Base year for this index was 1939. This index was replaced in 1955 by a quarterly index. The weighting scheme of the quarterly index was established on an index house. This index house was a residential construction in 3 storeys with 6 staircases and 36 apartments. In this index 1955 was base year. It was still calculated in 1972 for the sake of long-term contracts even if new indices were published from

1969 and 1971. These two new indices were construction cost indices for one-family houses and a block of flats. As a new concept there were calculated indices by profession and by building parts. The former construction cost index replaced the two indices for one-family houses and a block of flats in 1989. 1987 is base year. The change from two to one index was made because there was no longer any significant difference between the method in construction and choice of materials.

The present construction cost index is once again divided into an index for one-family houses and one for multi-family houses and thus meets the demands from the users of the index. 2003 is base year.

*Differences in classification:* As mentioned above only one total construction cost index was published until the publication of the two indices for one-family houses and a block of flats in 1969 and 1971. Hereafter, indices were calculated by profession and by building parts.

*Differences in the concept of price:* The monthly construction cost index published from 1939 to 1955 was calculated on the basis of information from the Wholesale price index about 20 of the most important construction materials. The labour costs were calculated on the basis of changes in the collective agreed wages in the construction industry. The index included in this way the direct expenses and excluded cost of engineers and architects. In 1955 the concept of price was changed. After this Statistics Denmark collected prices for 132 of the most important or most representative materials. The collected prices were net prices i.e. the invoice prices the master had to pay the supplier of materials excluding general discounts and any profits and including any given duty (i.e. including purchase tax (oms) per 1.8.1962 and VAT per 3.7.1967). The labour costs were calculated on the basis of the current price list in the provinces. The price list was based on collective agreements including social contributions among other things allowance for public holiday.

In the two indices published from 1969 to 1989 a larger number of representative goods were used than in the earlier indices. The material cost index was calculated on the basis of gross prices excluding VAT. The material costs excluded masters fee and other profits. The labour cost index was calculated on the basis of price lists in the different construction trades.

The material cost index in the former construction cost index from 1987 was calculated on the basis of list prices and gathered information on producer prices deducted general discounts. The calculation of labour costs was made on the basis of collective agreement wages including compulsory employers' contributions. The former index is comparable with the indices from 1968 and because of the parallel calculation of the indices in the period from 1987 to 1989 it is possible to

regulate contracts back to 1968.

The material cost index in the present construction cost index is calculated on the basis of prices collected from the Price Index for Domestic Supply where both general and specific discounts are deducted. The labour cost index is calculated on the basis of the Indices of Average Earnings for the Private Sector which contains information on each employees earnings etc.

### **7.3 Coherence - cross domain**

The prices for the total labour costs are mainly collected from the Indices of Average Earnings for the Private Sector. The development of the indices of labour costs is not directly comparable to the development of the average earnings for the construction sector. This is among other things caused by the fact that in the labour cost indices, costs of all types of labour related to the construction process are included. Thus, even if a construction process mainly concerns one type of labour, costs related to other types of labour partaking in the process are included in the calculations. The labour costs in the different types of construction processes are composed as follows:

- *Earth- and concrete work:* Concrete and reinforced concrete work, earth and sewage work, landscaping, paving, plumbing, production management
- *Concrete slab work:* Concrete and reinforced concrete work
- *Brick laying:* Brick laying, brick laying assistance, concrete and reinforced concrete work, production management
- *Carpentry:* Carpentry/joinery, roofing, flooring, production management, concrete and reinforced concrete work, plumbing, forging
- *Joinery:* Carpentry/joinery, concrete and reinforced concrete work, production management
- *Painting:* Painting, cleaning, concrete and reinforced concrete work, production management, carpentry/joinery
- *Heating and sanitary engineering:* Plumbing, insulation, production management, concrete and reinforced concrete work
- *Electrical work:* Electrical work, concrete and reinforced concrete work, production management, paving

Another explanation is that in the Indices of Average Earnings all employees that are employed in enterprises belonging to the construction sector including engineers and administrative personnel are included. In the construction cost index only persons that are directly involved in building activities are included.

In the construction cost index only employees that are present in two consecutive quarters are included. A number of persons are thus excluded compared to the Indices of Average Earnings.

Further more, in the construction cost index the different professions are included in the index with different weights depending on the profession's importance for the total construction costs. The development of some professions' average earnings consequently has greater impact on the index than others.

Prices for materials and equipment are mainly collected from the Price Index for Domestic Supply. These indices are not directly comparable to the indices for materials in the construction cost index. This is caused by the fact that to each representative goods a number of selected goods are attached and by the fact that for calculating each materiel index a number of representative goods are included using different weights.

#### **7.4 Coherence - internal**

Not relevant for these statistics.

### **8 Accessibility and clarity**

The statistics are published in *Nyt fra Danmarks Statistik* (News from Statistics Denmark) and in *Byggeri og boligforhold* (Construction and housing) which appears in *Konjunkturstatistik* (Main indicators).

Yearly publications: *Statistical Yearbook* and *Statistical ten-year review*

Statistics are available from Statbank Denmark at: ([www.Statbank.dk](http://www.Statbank.dk)): [Byg4](#) and [Byg5](#).

Furthermore, it is possible to subscribe to the construction index by postcards.

#### **8.1 Release calendar**

The publication date appears in the release calendar. The date is confirmed in the weeks before.

#### **8.2 Release calendar access**

The Release Calendar can be accessed on our English website: [Release Calendar](#).

#### **8.3 User access**

Statistics are always published at 8:00 a.m. at the day announced in the release calendar. No one outside of Statistics Denmark can access the statistics before they are published.

#### **8.4 News release**

[News release](#) for construction cost index for residential buildings.

#### **8.5 Publications**

The statistics are published in *Nyt fra Danmarks Statistik* (News from Statistics Denmark) and in *Byggeri og boligforhold* (Construction and housing) which appears in *Konjunkturstatistik* (Main indicators).

Yearly publications: *Statistical Yearbook* and *Statistical ten-year review*

Statistics are available from Statbank Denmark at: ([www.Statbank.dk](http://www.Statbank.dk)): [Byg4](#) and [Byg5](#).

Furthermore, it is possible to subscribe to the construction index by postcards.

#### **8.6 On-line database**

## 8.7 Micro-data access

Basis material is stored in a register. The system for calculating the indices is constructed so that it is possible to produce special indices. The basis in the system is the BC/SfB-Building Board, and within the framework of this Board there are vast opportunities of constructing special customised indices: Examples are:

- Index for a specific building part
- Index for one of the eight buildings
- Index for other kinds of buildings, i.e. office buildings and universities

## 8.8 Other

The Construction Cost Index for Residential Buildings is transmitted to Eurostat on a quarterly basis in accordance with regulations 1165/98 and 588/2001.

## 8.9 Confidentiality - policy

All statistics in Statistics Denmark follow the data confidentiality protocol of Statistics Denmark. For the construction cost index for residential buildings only aggregated indices are published, thus discretion does not apply to this statistic.

## 8.10 Confidentiality - data treatment

All statistics in Statistics Denmark follow the data confidentiality protocol of Statistics Denmark. For the construction cost index for residential buildings only aggregated indices are published, thus discretion does not apply to this statistic.

## 8.11 Documentation on methodology

A further description of the method used is available in: The publication *Bygge- og anlægsvirksomhed* (Construction industry) which appears in the series *Statistiske Efterretninger* (Statistical News) no: 2003:33.

## 8.12 Quality documentation

Results from the quality evaluation of products and selected processes are available in detail for each statistics and in summary reports for the Working Group on Quality.

## 9 Contact

The administrative placement of this statistic is in the division of Prices and Consumption. The person responsible is Sigrid Krogstrup Jensen, tel. +45 3917 3456, e-mail: sij@dst.dk

### 9.1 Contact organisation
